E5 Wind turbine model

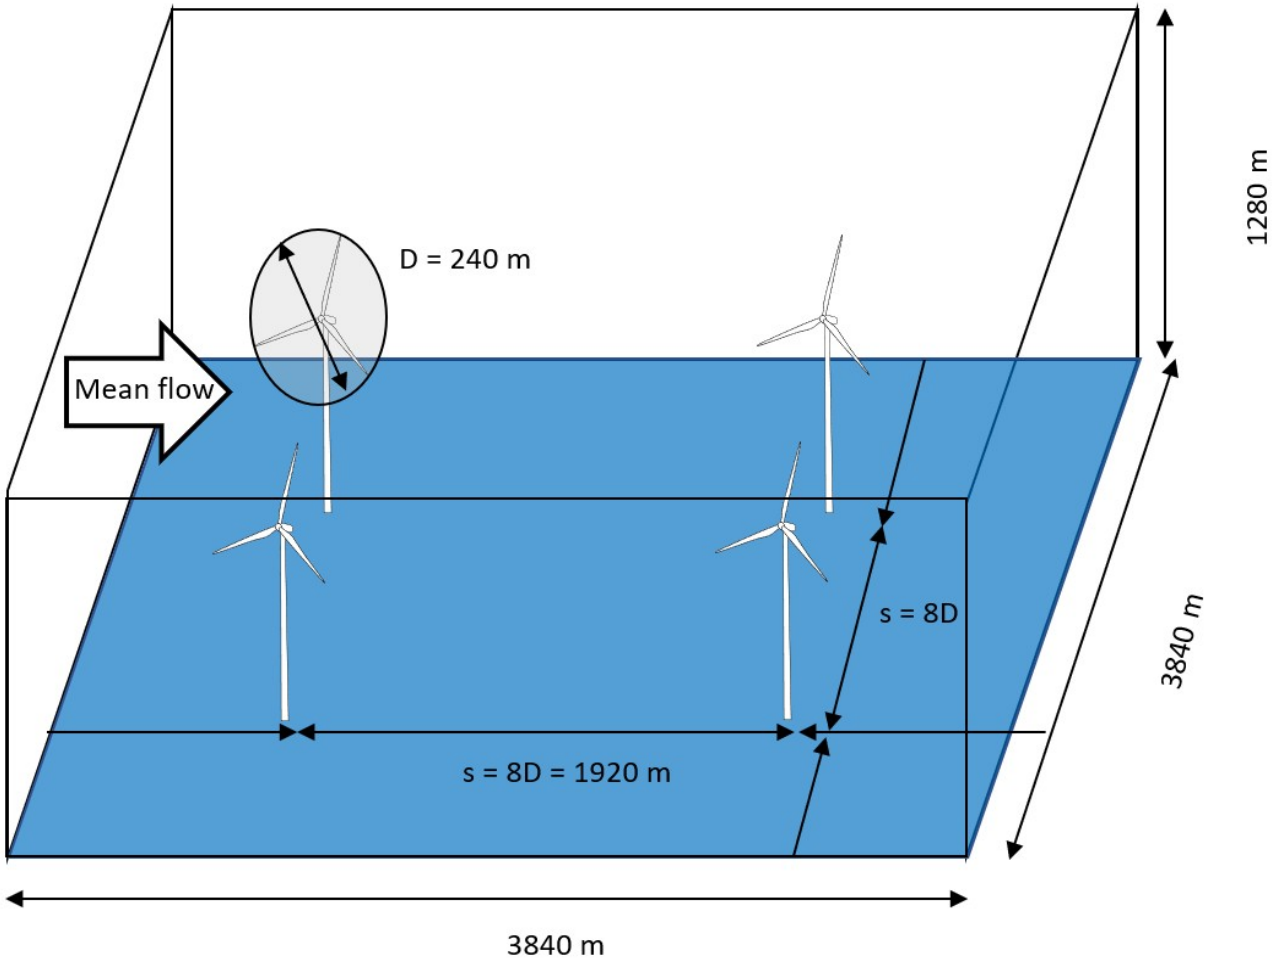
E5 Wind turbine model

Introduction

- In this exercise you will simulate a 1-4 wind turbines in a conventionally neutral boundary layer.
- The wind farm consists of max. 4 wind turbines.
- The IEA 15 MW Reference wind turbine is used, it has:
  - a rotor diameter of D = 240 m,
  - a hub height of h = 150 m and
  - a rated power of 15 MW
- Cyclic boundary conditions are applied in x- and y-direction, so that the wind farm is effectively infinitely large.

E5: Wind turbine model

Setup with 4 turbines



E5: Wind turbine model

Setup

- **Physics**
  - Flow is initialized with vertically constant velocity profiles, corresponding to the geostrophic wind: u(z) = ug_surface, v(z) = vg_surface
  - initial potential temperature profile is constant up to z = 500 m and has a lapse rate of +0.35 K/(100 m) above
  - Flow is driven by a geostrophic wind of ug, vg = 12.0, -3.8 m/s
    - This results in a wind direction at hub height that is approximately aligned with the x-axis after 2 h.
  - No surface heating or cooling → neutral boundary layer
- **Numerics**
  - grid spacing is 40 m → 6 grid points per rotor diameter
  - cyclic boundary conditions along x and y → infinite wind farm
  - Data output of instantaneous and averaged data every 30 minutes
- **Wind turbines**
  - 4 equally spaced wind turbines, spacing 8 rotor diameters = 1920 m
  - hub height = 150.0 m, Rotor diameter = 240 m
  - active pitch and yaw control

E5: Wind turbine model

How to start the simulation

- The wind turbine model requires NetCDF version 4. Do the following steps in your installation directory:
  - create a copy of the `.palm.config.default` file and rename it to: `.palm.config.default_netcdf4`
  - In this file add „ `-D__netcdf4“ to the „%cpp_options …“`
  - recompile palm using the new config: `palmbuild -c default_netcdf4`

- Provide the input files
  - create a new directory "`e5_wtm_exercise/INPUT`" in your "`JOBS`" directory
  - copy the input files `e5_wtm_exercise_p3d` and `e5_wtm_exercise_wtm` to the `INPUT` directory

- Start the simulation using the new configuration file (adapt if you have more cores available!):
  - `palmrun -r e5_wtm_exercise -c default_netcdf4 -a “d3#” -X 4 -T 4`

Questions

Part 1: wind park simulation

1. Is the mean flow in a steady state at the end of the simulation (t = 2 h)?
   - use: `plot_time_series.py, plot_profiles.py`
2. Describe the mean velocity field at hub height, especially near the turbines. Explain how it is related to the pressure field.
   - use: `plot_xy_av.py`
3. Are the wakes rotating? In which direction and why?
   - use: `plot_xy_av.py, plot_xz_av.py`

E5: Wind turbine model

Questions & Tasks

Part 2: single wind turbine & wake interaction

4. Reduce the set-up to a single turbine located at the center of the domain. Vary the geostropic wind speed in and try to reproduce the power curve of the turbine!

   Hints:

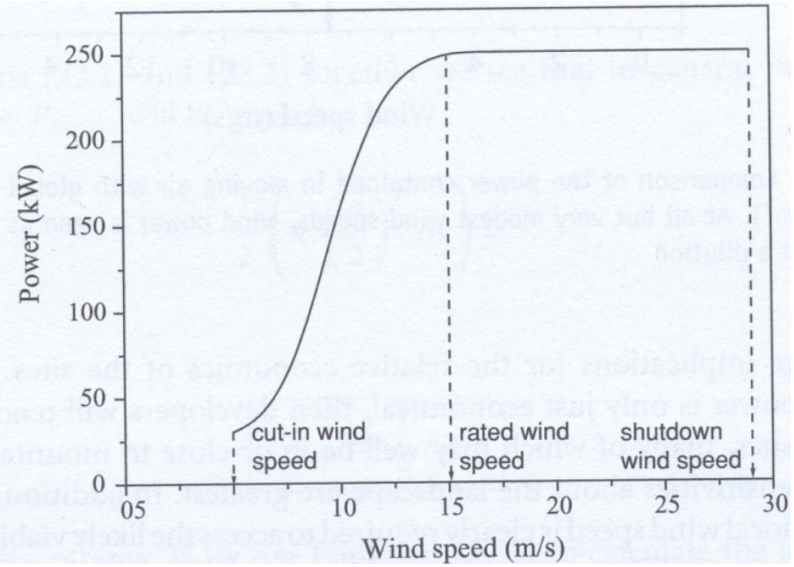
   - you can set `vg_surface = 0.0` for a single turbine set-up
   - you might use MS Excel/LO Spreadsheet for that purpose

5. Place a 2nd turbine in the wake of the first one using different spacings:

   2 D, 5 D, 8 D

   How do the turbines interact regarding wind speed recovery?

   What distance between turbines do you recommend based on these lightweight simulations?



Example of a power curve
